Executive Summary

Type: Trojan

Targeted Platforms: Windows 7, 8, 10

Disguise: Masquerades as legitimate Dependency Walker software

Persistence: Utilizes Busybox for establishing long-term presence

Behavior: Dropped 2 execute files. Operates in stealth mode and deploys Command and Control (C2)

The identified malware has been classified as a trojan, with the initial executable file named depends.exe serving as a dropper responsible for deploying two distinct executable files. One of these files, depends_.exe, is verified as a legitimate component, while the second file, named httpd.exe, is designed to establish persistence on the compromised system. Upon execution of depends.exe, a netsh command is employed to create a firewall configuration, facilitating communication with the malicious server for httpd.exe.

It should be noted that with each instance of depends.exe execution, a new iteration labeled depends__.exe is generated. However, it is noteworthy that the persistence component, httpd.exe, remains singular. This persistent executable is programmed to collect and transmit victim data to the designated malware server upon activation.

The orchestration of this malware underscores a deliberate and methodical approach, utilizing a multi-stage deployment strategy for maintaining a persistent presence on the compromised system, coupled with the exfiltration of sensitive data to the external server.

YARA rules can be found under the YARA section of the report. These rules identify the malware components in this project.

DEPENDS.EXE

Window API [1]

These functions are employed to modify the memory of another process. Malicious software may utilize them for the following purposes:

- Allocating memory within a target process and subsequently copying the contents of an executable file into that allocated space. This effectively involves "injecting" the file into the memory of the target process.
- Initiating a process in a paused or suspended state, removing its existing memory mappings, and substituting them with malicious code. Subsequently, the process is resumed, allowing the malicious code to execute within the context of a genuine and legitimate process.

[VirtualAlloc](#)[VirtualFree](#)[VirtualProtect](#)[VirtualQuery](#)[VirtualQuery](#)[VirtualProtect](#)[VirtualAlloc](#)[VirtualFree](#)[VirtualProtect](#)[VirtualAlloc](#)[VirtualFree](#)[VirtualProtect](#)[VirtualQuery](#)[VirtualQuery](#)[VirtualProtect](#)[VirtualAlloc](#)[VirtualFree](#)

| |
|---|
| GetThreadPriority |
| GetTickCount |
| IsDebuggerPresent |
| QueryPerformanceCounter |
| QueryPerformanceFrequency |
| IsDebuggerPresent |
| GetThreadContext |
| GetCurrentProcessId |
| GetThreadPriority |
| QueryPerformanceFrequency |
| GetTickCount |
| QueryPerformanceCounter |
| GetStartupInfo |
| GetProductInfo |
| GetUserName |
| GetSystemDirectory |
| GetLogicalDrives |
| GetDriveType |
| GetVersionEx |
| GetComputerName |
| GetSystemInfo |
| GetTimeZoneInformation |
| GetDateFormat |
| GetTimeFormat |
| GetWindowsDirectory |
| GetEnvironmentVariable |
| GetLocalTime |
| SearchPath |

- The malware employs the "IsDebuggerPresent" API to ascertain the presence of a debugger, alongside a suite of other APIs aimed at uncovering various details about the computer. These include "GetStartupInfo," "GetUserName," "GetProductInfo," "GetTimeZoneInformation," "GetWindowsDirectory," and "GetLocalTime," among others. This comprehensive approach indicates a systematic effort by the malware to gather extensive information about the victim's computer.

Contain ".bss"

| value | property |
|-------------------------|---------------------------------------|
| section[6] | section |
| .bss | name |
| n/a | footprint > sha256 |
| n/a | entropy |
| n/a | file-ratio (90.23%) |
| 0x00000000 | raw-address (begin) |
| 0x00000000 | raw-address (end) |
| 0x00000000 (0 bytes) | raw-size (1121280 bytes) |
| 0x00111000 | virtual-address |
| 0x00001050 (4176 bytes) | virtual-size (1120291 bytes) |
| 0xC0600080 | characteristics |
| x | read |
| x | write |
| - | execute |
| - | share |
| - | self-modifying |
| x | virtual |

- The "Depend.exe" executable may utilize the ".bss" section for tasks such as process injection, where it prepares code for injection in a zero-initialized space, and for storing obfuscated information, evading detection due to the non-signature-matching nature of the data and lesser scrutiny compared to other sections like ".text" or ".data".

Long and repeated name functions

The presence of excessively lengthy function names within the 'depends.exe' executable may serve as an indication of potentially nefarious activities or efforts at code obfuscation.

35     return;
```

Ghidra

- The “**WriteProcessMemory**” function is integral to modifying the memory of a target process and is often leveraged in malicious exploits to alter a process's functionality.
- The “**CreateRemoteThread**” function, known for initiating a thread in another process's space, raises concerns due to its association with code injection techniques, which are

hallmarks of malware operations, particularly in the creation of Remote Access Trojans (RATs).

| | 64 73 2e ... | | |

Ghidra

- The executable in question, designated as "depends.exe", appears to be engaging in behavior consistent with the execution of a shell command. Based upon the accumulated evidence, it is posited that this malware attempts to execute a shell process and consequently deploys two executable files. The first bears the identical name "depends.exe", while the second is identified as "httpd.exe". The latter may be implicated in the establishment of a Command and Control (C2) infrastructure, or it may function as a component of a Remote Access Trojan (RAT),

Process Monitor

| | | | |
|---|--------------------|-------------|--------|
|  httpd.exe | 12/14/2023 7:06 PM | Application | 632 KB |
|  depends.exe | 12/14/2023 7:06 PM | Application | |
|  depends7SpUz4Ki.exe | 12/14/2023 7:06 PM | Application | |

C:\User\IEUser\AppData\Temp

| | | | | | |
|---|-------|----------|----------|------------------------------------|----------------|
|  procexp64.exe | 0.1 / | 20,472 K | 44,712 K | 6416 Sysinternals Process Explorer | Sysinternals - |
|  httpd.exe | | 1,036 K | 4,628 K | 3768 BusyBox multi-call binary | frperry.org |

Process Explorer

- Upon initiation, the "depends.exe" file executes a routine that results in the placement of three executable files within the "C:\Users\IEUser\AppData\Temp" directory. Notably, the tool Process Monitor fails to register the creation of "httpd.exe" within this directory, suggesting the possibility that it may have been deployed through a shell execution command. Furthermore, the operation of "httpd.exe" proceeds covertly, evading detection, with its activity only discernible through the use of Process Explorer.

HTTPD.EXE

Timestamp

[Temp\httpd.exe]

| Offset | Name | Value | Meaning |
|--------|-----------------|-------|-----------------------------------|
| 84 | Machine | 8664 | AMD64 (K8) |
| 86 | Sections Count | b | 11 |
| 88 | Time Date Stamp | 0 | Thursday, 01.01.1970 00:00:00 UTC |

PEBear

- The timestamp affixed to the header of "httpd.exe" is conspicuously archaic, recorded as Thursday, January 1st, 00:00:00 UTC. This anachronistic timestamp may be a deliberate attempt by the malware to mislead both users and automated security systems into regarding the file as an established, and thus ostensibly innocuous, component of the system's infrastructure.

Firewall Rule

| Inbound Rules | | | | | | | |
|---------------|----------------|----------|------------|-------------|------------------|--|----------|
| Name | Group | Profile | Enabled | Action | Override | Program | Location |
| 1337 | | All | Yes | Allow | No | C:\Users\IEUser\AppData\Local\Temp\httpd.exe | Any |
| Local Address | Remote Address | Protocol | Local Port | Remote Port | Authorized Users | Authorized Computers | |
| Any | Any | Any | Any | Any | Any | Any | |

Window Firewall

- Upon execution, the executable "Depends.exe" proceeds to establish a persistent element, "httpd.exe," on the system. Concurrently, it executes a shell command utilizing

netsh to create an inbound firewall rule. This rule, identified as "1337," is configured to authorize "httpd.exe" to operate across any port. Additionally, the configuration of this rule permits its utilization by any user account on the system.

Busybox and RAT

```

191 LAB_1400137b4:
192     pcVar21 = "busybox --install [-s] [-u|DIR]";
193     uVar6 = FUN_140010410("busybox --install [-s] [-u|DIR]", ppDVar14, param_3, param_4);
194 }
195 else {
196     ppDVar14 = (DWORD **) (ppbVar24 + DAT_14007e06c);
197     unaff_RSI = *ppDVar14;
198     uVar6 = uVar5 & 2;
199     if (unaff_RSI != (DWORD *)0x0) {
200         if ((uVar6 == 0) && (ppDVar14[1] == (DWORD *)0x0)) goto LAB_1400137dc;
201         goto LAB_1400137b4;
202     }
203 }

```

Ghidra

- Upon examination in Ghidra, it has been observed that the httpd.exe executable is utilizing BusyBox utilities. The use of BusyBox in this context may raise concerns regarding the potential for unauthorized activities. This concern is further substantiated by the detection of BusyBox establishing a secure SSL/TLS connection with a remote server. Notably, such connections facilitate encrypted communication between the web server and the client's web browser, remaining transparent to the user.

```

Decompile: UndefinedFunction_1400718c0 - (httpd.exe)
191     pFVar13 = (FILE *)FUN_140076150((short *)(_Memory + 1));

240 }

```

Ghidra

- Corroborating our initial findings, we successfully identified the function tasked with establishing a server connection to handle incoming requests, labeled as "UndefinedFunction_1400718c0." Within this function, there are discernible references to host details, User-Agent strings, and Proxy-Authorization parameters. This evidence strongly suggests that the malware is configured to set up a connection to a remote

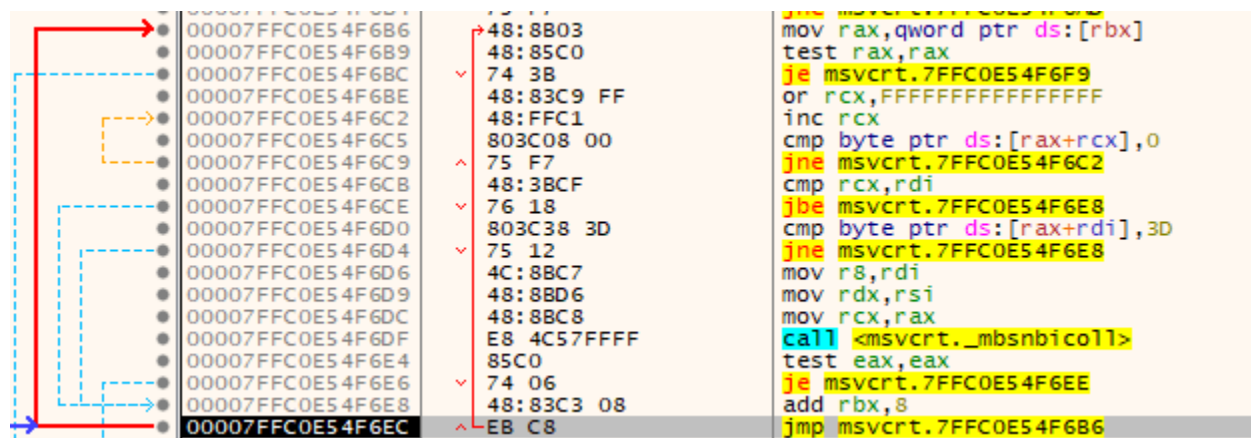

server, likely for the purposes of establishing a Remote Access Trojan (RAT) operation, thereby enabling unauthorized access and control over the infected system.

| | | | | | |
|-------------|------|-------|--------|---------|-------|
| httpd.exe | 6784 | TCP | Listen | 0.0.0.0 | 80 |
| System | 4 | TCP | Listen | 0.0.0.0 | 445 |
| System | 4 | TCP | Listen | 0.0.0.0 | 5985 |

| System | 4 | TCP | Listen | 0.0.0.0 | 47001 |
| httpd.exe | 6784 | TCPv6 | Listen | :: | 80 |

TCPView

- Upon preliminary examination, it has been observed that upon execution, the malware initiates a web server that binds to port 80 on the host system. This action suggests that the malware possesses the functionality to act as a rudimentary web server, utilizing port 80, which is traditionally reserved for HTTP traffic. Notwithstanding the activation of this local server, there is no evidence of subsequent external network communications.
- Httpd appears to be a legitimate program. The executable is a daemon, this is when it runs on a web server to handle incoming HTTP requests from clients, such as web browsers, and serves web content in response

Data Collection

x64dbg

- Upon execution of "httpd.exe" within the x64dbg environment, this particular assembly code block is observed to be operational. It is postulated that this block constitutes a segment of a function designed to retrieve an array of data from the target computer. This is inferred from the function's traversal across critical file paths and configurations, potentially leveraging environment variables. Such activity appears to be integral to the data acquisition process, specifically focusing on the C drive.

C:\Windows\Prefetch\NETSH.EXE-3DD790C5.pf - Microsoft network shell file for allowing local or remote network device configuration

Analysis

Creation of firewall rule named “1337” towards application httpd.exe and allowing all connections over it is highly suspect, as an enabled means of connection into the host. Various other connection interfaces and protocols including IPSec, NetTrace, and Netsh.exe are modified or established.

Yara

A. Project 4 Yara rules to identify malware components

```
import "hash"
import "pe"

rule proj4 {

  strings:
    $exe_0x = { 4D 5A } // Standard exe initializer
    $httpd_string = "@httpd.exe" //Suspect executable call
    $1337_0x = { 31 33 33 37 } //Firewall rule catch
    $shell_execute = "ProfileSimulateShellExecute" //Not present in legit version (checked with HxD)

  condition:
    $exe_0x at 0 and
    hash.md5(0, filesize) == "9ffd63ce0c331b651386063ce2e541e3" and //MD5 File hash
    $httpd_string and
    $1337_0x and
    $shell_execute and
    pe.timestamp != 1162190996 // Compiler timestamp of the official program (same version)

}

// netsh advfirewall firewall add rule name=1337 dir=in action=allow program="C:\\Users\\IEUser\\AppData\\Local\\Temp\\httpd.exe\" enable=yes
```
